

Lexical Analysis and Lexical Analyzer Generators

Chapter 3

The Reason Why Lexical Analysis is a Separate Phase

- Simplifies the design of the compiler
 - LL(1) or LR(1) parsing with 1 token lookahead would not be possible (multiple characters/tokens to match)
- Provides efficient implementation
 - Systematic techniques to implement lexical analyzers by hand or automatically from specifications
 - Stream buffering methods to scan input
- Improves portability
 - Non-standard symbols and alternate character encodings can be normalized (e.g. UTF8, trigraphs)

Interaction of the Lexical Analyzer with the Parser

Attributes of Tokens

y := 31 + 28*x

Lexical analyzer

<id, "y"> **<assign, >** **<num, 31>** **<'+', >** **<num, 28>** **<'*', >** **<id, "x">**

token

(lookahead)

tokenval

(token attribute)

Parser

Tokens, Patterns, and Lexemes

- A *token* is a classification of lexical units
 - For example: **id** and **num**
- *Lexemes* are the specific character strings that make up a token
 - For example: **abc** and **123**
- *Patterns* are rules describing the set of lexemes belonging to a token
 - For example: “*letter followed by letters and digits*” and “*non-empty sequence of digits*”

Specification of Patterns for Tokens: *Definitions*

- An *alphabet* Σ is a finite set of symbols (characters)
- A *string* s is a finite sequence of symbols from Σ
 - $|s|$ denotes the length of string s
 - ε denotes the empty string, thus $|\varepsilon| = 0$
- A *language* is a specific set of strings over some fixed alphabet Σ

Specification of Patterns for Tokens: *String Operations*

- The *concatenation* of two strings x and y is denoted by xy
- The *exponentiation* of a string s is defined by

$$\begin{aligned}s^0 &= \varepsilon \\ s^i &= s^{i-1}s \quad \text{for } i > 0\end{aligned}$$

note that $s\varepsilon = \varepsilon s = s$

Specification of Patterns for Tokens: *Language Operations*

- *Union*

$$L \cup M = \{s \mid s \in L \text{ or } s \in M\}$$

- *Concatenation*

$$LM = \{xy \mid x \in L \text{ and } y \in M\}$$

- *Exponentiation*

$$L^0 = \{\varepsilon\}; \quad L^i = L^{i-1}L$$

- *Kleene closure*

$$L^* = \cup_{i=0, \dots, \infty} L^i$$

- *Positive closure*

$$L^+ = \cup_{i=1, \dots, \infty} L^i$$

Specification of Patterns for Tokens: *Regular Expressions*

- Basis symbols:
 - ε is a regular expression denoting language $\{\varepsilon\}$
 - $a \in \Sigma$ is a regular expression denoting $\{a\}$
- If r and s are regular expressions denoting languages $L(r)$ and $M(s)$ respectively, then
 - $r \mid s$ is a regular expression denoting $L(r) \cup M(s)$
 - rs is a regular expression denoting $L(r)M(s)$
 - r^* is a regular expression denoting $L(r)^*$
 - (r) is a regular expression denoting $L(r)$
- A language defined by a regular expression is called a *regular set*

Specification of Patterns for Tokens: *Regular Definitions*

- Regular definitions introduce a naming convention with name-to-regular-expression bindings:

$$d_1 \rightarrow r_1$$

$$d_2 \rightarrow r_2$$

...

$$d_n \rightarrow r_n$$

where each r_i is a regular expression over

$$\Sigma \cup \{d_1, d_2, \dots, d_{i-1}\}$$

- Any d_j in r_i can be textually substituted in r_i to obtain an equivalent set of definitions

Specification of Patterns for Tokens: *Regular Definitions*

- Example:

letter \rightarrow **A** | **B** | ... | **Z** | **a** | **b** | ... | **z**

digit \rightarrow **0** | **1** | ... | **9**

id \rightarrow **letter** (**letter** | **digit**)^{*}

- Regular definitions cannot be recursive:

digits \rightarrow **digit digits** | **digit** *wrong!*

Specification of Patterns for Tokens: *Notational Shorthand*

- The following shorthands are often used:

$$r^+ = rr^*$$

$$r^? = r \mid \varepsilon$$

$$[\mathbf{a-z}] = \mathbf{a} \mid \mathbf{b} \mid \mathbf{c} \mid \dots \mid \mathbf{z}$$

- Examples:

digit \rightarrow **[0-9]**

num \rightarrow **digit⁺ (. digit⁺)? (E (+ | -)? digit⁺)?**

Regular Definitions and Grammars

Grammar

$$\begin{aligned} stmt &\rightarrow \mathbf{if} \, expr \, \mathbf{then} \, stmt \\ &\quad | \, \mathbf{if} \, expr \, \mathbf{then} \, stmt \, \mathbf{else} \, stmt \\ &\quad | \, \varepsilon \end{aligned}$$

$$\begin{aligned} expr &\rightarrow term \, \mathbf{relop} \, term \\ &\quad | \, term \end{aligned}$$

$$\begin{aligned} term &\rightarrow \mathbf{id} \\ &\quad | \, \mathbf{num} \end{aligned}$$

Regular definitions

$$\mathbf{if} \rightarrow \mathbf{i} \mathbf{f}$$

$$\mathbf{then} \rightarrow \mathbf{t} \mathbf{h} \mathbf{e} \mathbf{n}$$

$$\mathbf{else} \rightarrow \mathbf{e} \mathbf{l} \mathbf{s} \mathbf{e}$$

$$\mathbf{relop} \rightarrow < \mid <= \mid <> \mid > \mid >= \mid =$$

$$\mathbf{id} \rightarrow \mathbf{letter} \, (\, \mathbf{letter} \mid \mathbf{digit} \,)^*$$

$$\mathbf{num} \rightarrow \mathbf{digit}^+ \, (\, . \, \mathbf{digit}^+ \,)? \, (\, \mathbf{E} \, (\mathbf{+} \mid \mathbf{-})? \, \mathbf{digit}^+ \,)?$$

Coding Regular Definitions in *Transition Diagrams*

relop \rightarrow < | <= | <> | > | >= | =

id \rightarrow letter (letter | digit)*

Coding Regular Definitions in Transition Diagrams: Code

15

```
token nexttoken()
{ while (1) {
    switch (state) {
    case 0: c = nextchar();
        if (c==blank || c==tab || c==newline) {
            state = 0;
            lexeme_beginning++;
        }
        else if (c=='<') state = 1;
        else if (c=='=') state = 5;
        else if (c=='>') state = 6;
        else state = fail();
        break;
    case 1:
        ...
    case 9: c = nextchar();
        if (isletter(c)) state = 10;
        else state = fail();
        break;
    case 10: c = nextchar();
        if (isletter(c)) state = 10;
        else if (isdigit(c)) state = 10;
        else state = 11;
        break;
    ...
}
```

Decides the
next start state
to check

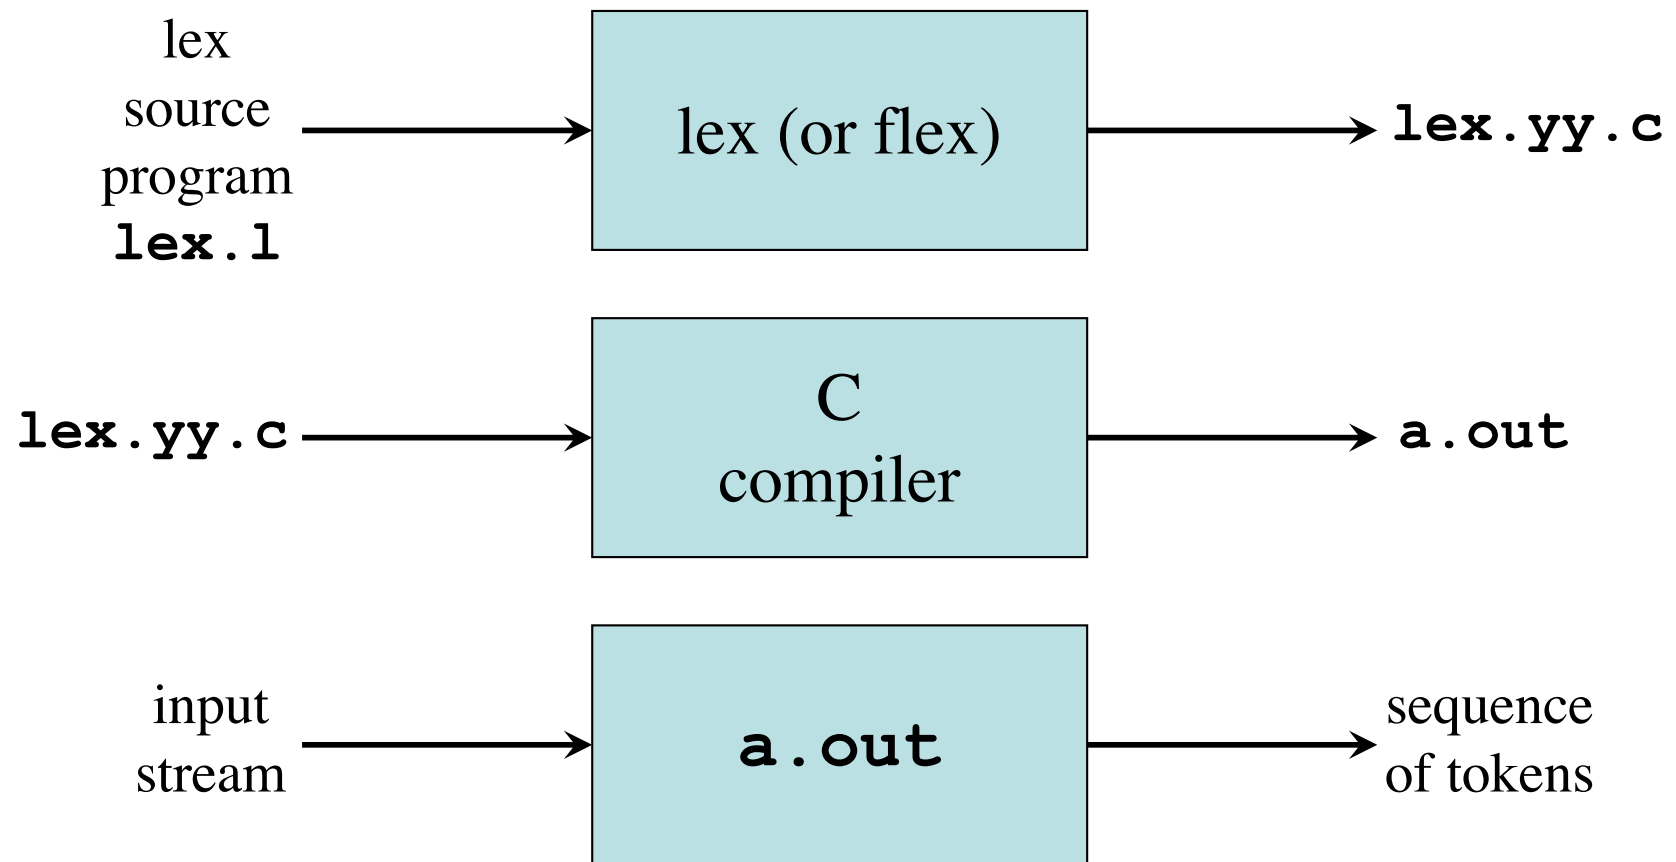

```
int fail()
{ forward = token_beginning;
  switch (start) {
    case 0: start = 9; break;
    case 9: start = 12; break;
    case 12: start = 20; break;
    case 20: start = 25; break;
    case 25: recover(); break;
    default: /* error */
  }
  return start;
}
```

The Lex and Flex Scanner Generators

- *Lex* and its newer cousin *flex* are *scanner generators*
- Scanner generators systematically translate regular definitions into C source code for efficient scanning
- Generated code is easy to integrate in C applications

Creating a Lexical Analyzer with Lex and Flex

Lex Specification

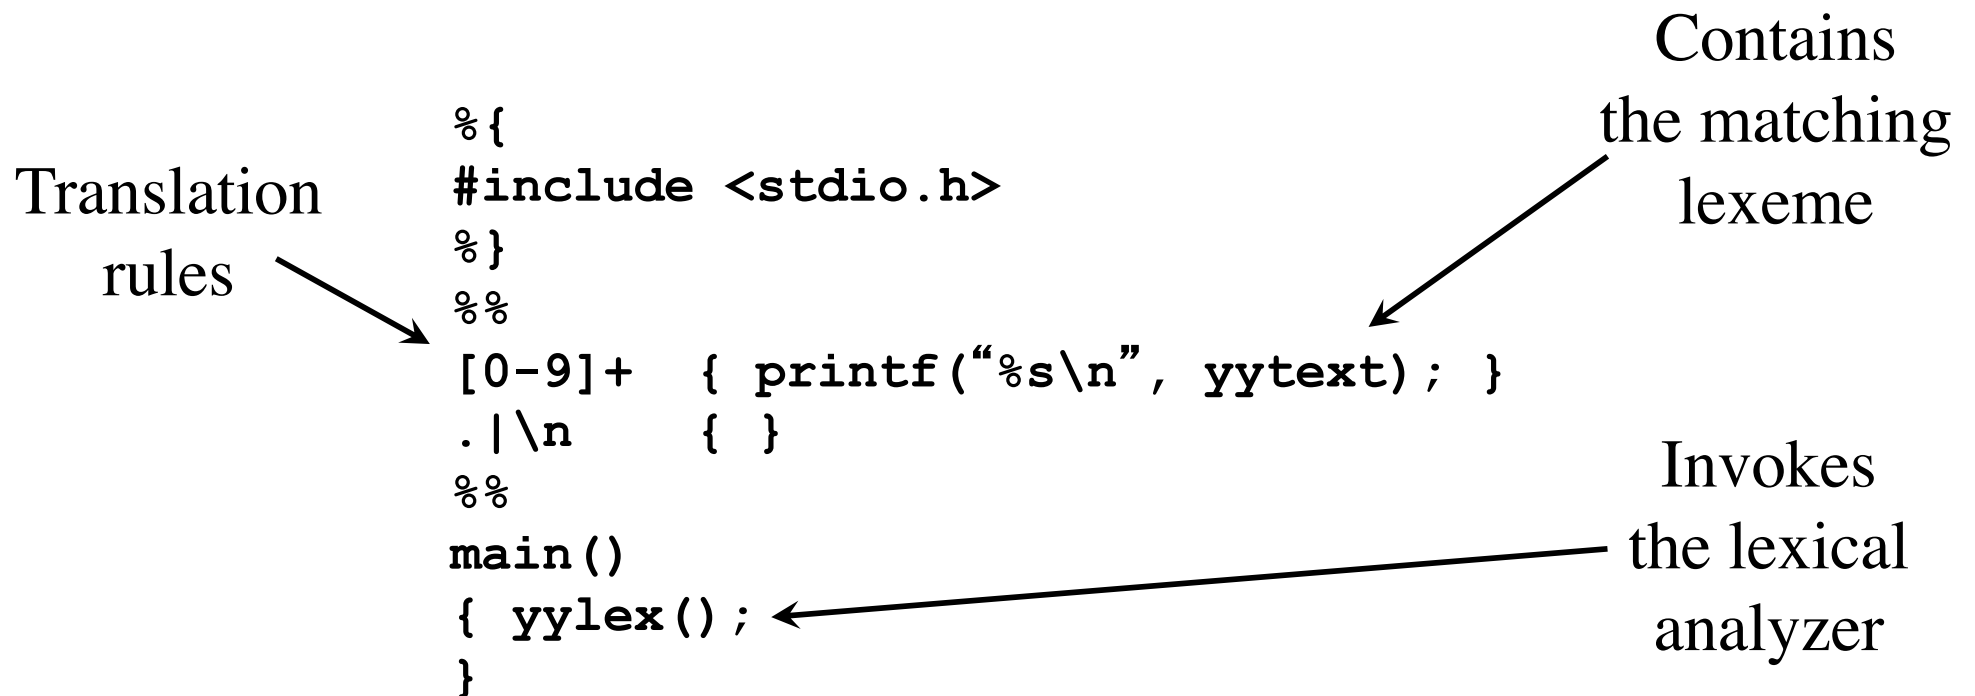

- A *lex specification* consists of three parts:
regular definitions, C declarations in `% { % }`
`%%`
translation rules
`%%`
user-defined auxiliary procedures
- The *translation rules* are of the form:

p_1	$\{ action_1 \}$
p_2	$\{ action_2 \}$
\dots	
p_n	$\{ action_n \}$

Regular Expressions in Lex

x	match the character x
\.	match the character .
"string"	match contents of string of characters
.	match any character except newline
^	match beginning of a line
\$	match the end of a line
[xyz]	match one character x , y , or z (use \ to escape -)
[^xyz]	match any character except x , y , and z
[a-z]	match one of a to z
r*	closure (match zero or more occurrences)
r+	positive closure (match one or more occurrences)
r?	optional (match zero or one occurrence)
r₁r₂	match r₁ then r₂ (concatenation)
r₁ r₂	match r₁ or r₂ (union)
(r)	grouping
r₁/r₂	match r₁ when followed by r₂
{d}	match the regular expression defined by d

Example Lex Specification 1

```
lex spec.1  
gcc lex.yy.c -ll  
./a.out < spec.1
```

Example Lex Specification 2

Translation
rules

```
%{  
#include <stdio.h>  
int ch = 0, wd = 0, nl = 0;  
%}  
delim      [ \t]+  
%%  
\n        { ch++; wd++; nl++; }  
^{delim}   { ch+=yylen; }  
{delim}    { ch+=yylen; wd++; }  
.          { ch++; }  
%%  
main()  
{ yylex();  
  printf("%8d%8d%8d\n", nl, wd, ch);  
}
```

Regular
definition

Example Lex Specification 3

Translation
rules

```
%{  
#include <stdio.h>  
%}  
digit      [0-9]  
letter     [A-Za-z]  
id         {letter} ({letter} | {digit})*  
%%  
{digit}+  { printf("number: %s\n", yytext); }  
{id}      { printf("ident: %s\n", yytext); }  
.  
%%  
main()  
{ yylex();  
}
```

Regular
definitions

Example Lex Specification 4

```

%{ /* definitions of manifest constants */
#define LT (256)
...
%}
delim      [ \t\n]
ws         {delim}+
letter     [A-Za-z]
digit      [0-9]
id         {letter}({letter}|{digit})*
number     {digit}+(\.{digit}+)?(E[+\-]?{digit}+)?
%%
{ws}       { }
if         {return IF;}
then       {return THEN;}
else       {return ELSE;}
{id}       {yyval = install_id(); return ID;}
{number}   {yyval = install_num(); return NUMBER;}
"<"       {yyval = LT; return RELOP;}
"<="     {yyval = LE; return RELOP;}
"="       {yyval = EQ; return RELOP;}
"<>"     {yyval = NE; return RELOP;}
">"       {yyval = GT; return RELOP;}
">="     {yyval = GE; return RELOP;}
%%
int install_id()
...

```

Install **yytext** as
identifier in symbol table

Design of a Lexical Analyzer Generator

- Translate regular expressions to NFA
- Translate NFA to an efficient DFA

Nondeterministic Finite Automata

- An NFA is a 5-tuple $(S, \Sigma, \delta, s_0, F)$ where

S is a finite set of *states*

Σ is a finite set of symbols, the *alphabet*

δ is a *mapping* from $S \times \Sigma$ to a set of states

$s_0 \in S$ is the *start state*

$F \subseteq S$ is the set of *accepting* (or *final*) *states*

Transition Graph

- An NFA can be diagrammatically represented by a labeled directed graph called a *transition graph*

$$S = \{0,1,2,3\}$$

$$\Sigma = \{\mathbf{a}, \mathbf{b}\}$$

$$s_0 = 0$$

$$F = \{3\}$$

Transition Table

- The mapping δ of an NFA can be represented in a *transition table*

$$\delta(0, \mathbf{a}) = \{0, 1\}$$

$$\delta(0, \mathbf{b}) = \{0\}$$

$$\delta(1, \mathbf{b}) = \{2\}$$

$$\delta(2, \mathbf{b}) = \{3\}$$

<i>State</i>	<i>Input</i> a	<i>Input</i> b
0	{0, 1}	{0}
1		{2}
2		{3}

The Language Defined by an NFA

- An NFA *accepts* an input string x if and only if there is some path with edges labeled with symbols from x in sequence from the start state to some accepting state in the transition graph
- A state transition from one state to another on the path is called a *move*
- The *language defined by* an NFA is the set of input strings it accepts, such as $(\mathbf{a} \mid \mathbf{b})^* \mathbf{abb}$ for the example NFA

Design of a Lexical Analyzer Generator: RE to NFA to DFA

Lex specification with
regular expressions

p_1 $\{ action_1 \}$
 p_2 $\{ action_2 \}$
 \dots
 p_n $\{ action_n \}$

NFA

DFA

From Regular Expression to NFA (Thompson's Construction)

Combining the NFAs of a Set of Regular Expressions

a $\{ action_1 \}$
abb $\{ action_2 \}$
a*b+ $\{ action_3 \}$

Simulating the Combined NFA

Example 1

Must find the *longest match*:

Continue until no further moves are possible

When last state is accepting: execute action

Simulating the Combined NFA

Example 2

When two or more accepting states are reached, the first action given in the Lex specification is executed

Deterministic Finite Automata

- A *deterministic finite automaton* is a special case of an NFA
 - No state has an ϵ -transition
 - For each state s and input symbol a there is at most one edge labeled a leaving s
- Each entry in the transition table is a single state
 - At most one path exists to accept a string
 - Simulation algorithm is simple

Example DFA

A DFA that accepts $(a \mid b)^*abb$

Conversion of an NFA into a DFA

- The *subset construction algorithm* converts an NFA into a DFA using:

$$\varepsilon\text{-closure}(s) = \{s\} \cup \{t \mid s \rightarrow_{\varepsilon} \dots \rightarrow_{\varepsilon} t\}$$

$$\varepsilon\text{-closure}(T) = \bigcup_{s \in T} \varepsilon\text{-closure}(s)$$

$$\text{move}(T, a) = \{t \mid s \rightarrow_a t \text{ and } s \in T\}$$

- The algorithm produces:

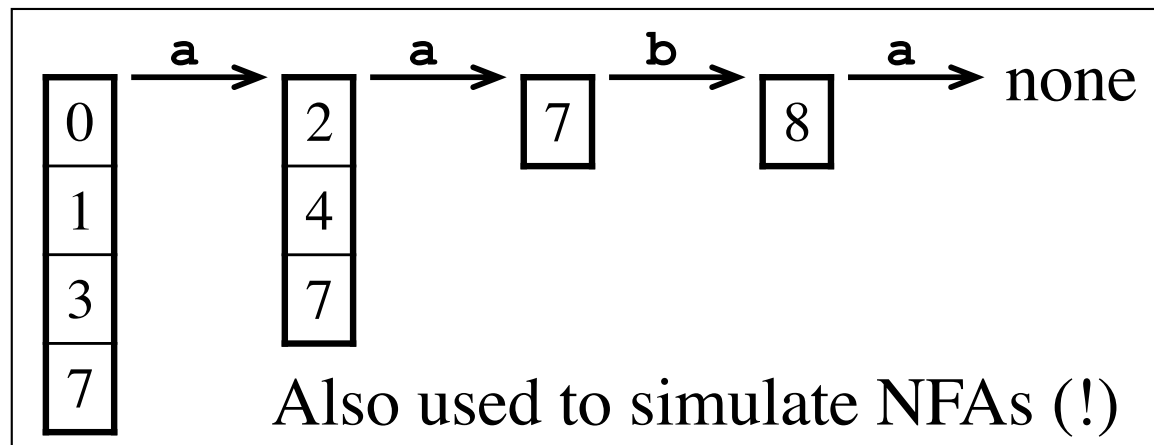

Dstates is the set of states of the new DFA
consisting of sets of states of the NFA

Dtran is the transition table of the new DFA

ϵ -closure and move Examples

ϵ -closure($\{0\}$) = $\{0,1,3,7\}$
 $move(\{0,1,3,7\}, \mathbf{a}) = \{2,4,7\}$
 ϵ -closure($\{2,4,7\}$) = $\{2,4,7\}$
 $move(\{2,4,7\}, \mathbf{a}) = \{7\}$
 ϵ -closure($\{7\}$) = $\{7\}$
 $move(\{7\}, \mathbf{b}) = \{8\}$
 ϵ -closure($\{8\}$) = $\{8\}$
 $move(\{8\}, \mathbf{a}) = \emptyset$

Simulating an NFA using *ε -closure* and *move*

```

 $S := \varepsilon\text{-closure}(\{s_0\})$ 
 $S_{prev} := \emptyset$ 
 $a := \text{nextchar}()$ 
while  $S \neq \emptyset$  do
     $S_{prev} := S$ 
     $S := \varepsilon\text{-closure}(\text{move}(S, a))$ 
     $a := \text{nextchar}()$ 
end do
if  $S_{prev} \cap F \neq \emptyset$  then
    execute action in  $S_{prev}$ 
    return “yes”
else    return “no”

```

The Subset Construction Algorithm

Initially, $\varepsilon\text{-closure}(s_0)$ is the only state in $Dstates$ and it is unmarked
while there is an unmarked state T in $Dstates$ **do**

 mark T

for each input symbol $a \in \Sigma$ **do**

$U := \varepsilon\text{-closure}(\text{move}(T, a))$

if U is not in $Dstates$ **then**

 add U as an unmarked state to $Dstates$

end if

$Dtran[T, a] := U$

end do

end do

Subset Construction Example 1

Dstates

$A = \{0, 1, 2, 4, 7\}$

$B = \{1, 2, 3, 4, 6, 7, 8\}$

$C = \{1, 2, 4, 5, 6, 7\}$

$D = \{1, 2, 4, 5, 6, 7, 9\}$

$E = \{1, 2, 4, 5, 6, 7, 10\}$

Subset Construction Example 2

Dstates

$A = \{0, 1, 3, 7\}$

$B = \{2, 4, 7\}$

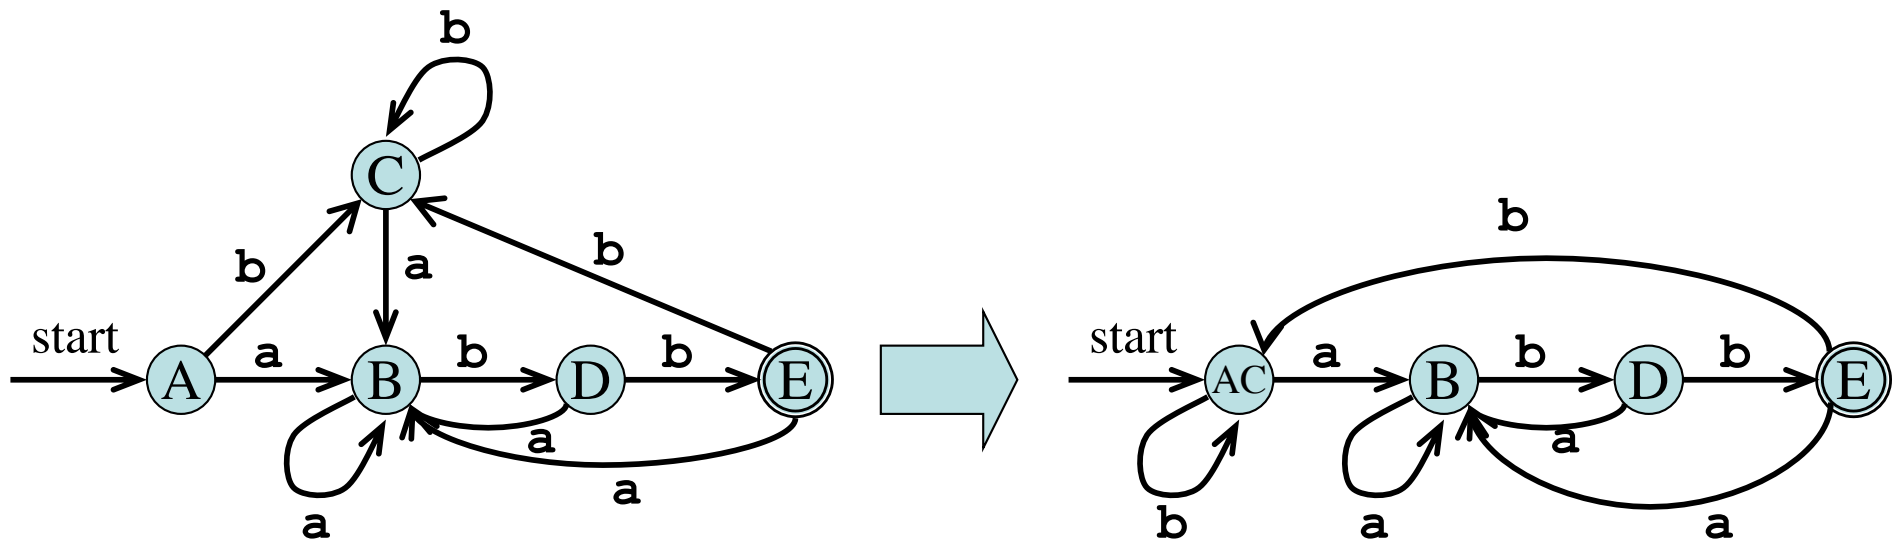

$C = \{8\}$

$D = \{7\}$

$E = \{5, 8\}$

$F = \{6, 8\}$

Minimizing the Number of States of a DFA

From Regular Expression to DFA Directly

- The “*important states*” of an NFA are those without an ε -transition, that is if $move(\{s\}, a) \neq \emptyset$ for some a then s is an important state
- The subset construction algorithm uses only the important states when it determines ε -closure($move(T, a)$)

From Regular Expression to DFA Directly (Algorithm)

- Augment the regular expression r with a special end symbol $\#$ to make accepting states important: the new expression is $r\#$
- Construct a syntax tree for $r\#$
- Traverse the tree to construct functions *nullable*, *firstpos*, *lastpos*, and *followpos*

From Regular Expression to DFA

Directly: Syntax Tree of $(a|b)^*abb\#$

From Regular Expression to DFA

Directly: Annotating the Tree

- *nullable(n)*: the subtree at node n generates languages including the empty string
- *firstpos(n)*: set of positions that can match the first symbol of a string generated by the subtree at node n
- *lastpos(n)*: the set of positions that can match the last symbol of a string generated by the subtree at node n
- *followpos(i)*: the set of positions that can follow position i in the tree

From Regular Expression to DFA

Directly: Annotating the Tree

Node n	$nullable(n)$	$firstpos(n)$	$lastpos(n)$
Leaf ε	true	\emptyset	\emptyset
Leaf i	false	$\{i\}$	$\{i\}$
$ \begin{array}{c} \\ / \quad \backslash \\ c_1 \quad c_2 \end{array} $	$nullable(c_1)$ or $nullable(c_2)$	$firstpos(c_1)$ \cup $firstpos(c_2)$	$lastpos(c_1)$ \cup $lastpos(c_2)$
$ \begin{array}{c} \bullet \\ / \quad \backslash \\ c_1 \quad c_2 \end{array} $	$nullable(c_1)$ and $nullable(c_2)$	if $nullable(c_1)$ then $firstpos(c_1) \cup$ $firstpos(c_2)$ else $firstpos(c_1)$	if $nullable(c_2)$ then $lastpos(c_1) \cup$ $lastpos(c_2)$ else $lastpos(c_2)$
$ \begin{array}{c} * \\ \\ c_1 \end{array} $	true	$firstpos(c_1)$	$lastpos(c_1)$

From Regular Expression to DFA

Directly: Syntax Tree of $(a|b)^*abb\#$

From Regular Expression to DFA

Directly: *followpos*

```
for each node  $n$  in the tree do
    if  $n$  is a cat-node with left child  $c_1$  and right child  $c_2$  then
        for each  $i$  in  $lastpos(c_1)$  do
             $followpos(i) := followpos(i) \cup firstpos(c_2)$ 
        end do
    else if  $n$  is a star-node
        for each  $i$  in  $lastpos(n)$  do
             $followpos(i) := followpos(i) \cup firstpos(n)$ 
        end do
    end if
end do
```

From Regular Expression to DFA

Directly: Algorithm

$s_0 := \text{firstpos}(\text{root})$ where root is the root of the syntax tree

$Dstates := \{s_0\}$ and is unmarked

while there is an unmarked state T in $Dstates$ **do**

 mark T

for each input symbol $a \in \Sigma$ **do**

 let U be the set of positions that are in $\text{followpos}(p)$

 for some position p in T ,

 such that the symbol at position p is a

if U is not empty and not in $Dstates$ **then**

 add U as an unmarked state to $Dstates$

end if

$Dtran[T, a] := U$

end do

end do

From Regular Expression to DFA

Directly: Example

Node	<i>followpos</i>
1	{1, 2, 3}
2	{1, 2, 3}
3	{4}
4	{5}
5	{6}
6	-

Time-Space Tradeoffs

<i>Automaton</i>	<i>Space (worst case)</i>	<i>Time (worst case)</i>
NFA	$O(r)$	$O(r \times x)$
DFA	$O(2^{ r })$	$O(x)$
